- Conclusion and Questions

Introduction to Apache Mahout

Apache Mahout is an environment for creating scalable, performant, machine-learning applications

Apache Mahout provides:

- A simple and extensible programming environment and framework for building scalable algorithms
- A variety of pre-made algorithms for Scala + Apache Spark, Apache Flink, H2O
- Samsara, a vector math experimentation environment with R-like syntax which works at scale
- Notebook Integration packaged with Apache Zeppelin

Recent Work on the Project

- Mahout-Samsara vector-math DSL released in August 2015 in 0.11.0 release
- New Mahout Book 'Apache Mahout: Beyond MapReduce' by Dmitriy Lyubimov and Andrew Palumbo - Feb 2016
- Support for Apache Flink as a backend execution engine added in 0.12.0 release - April 2016
- Integration with Apache Zeppelin Notebooks Nov 2016
- In Progress: Support for Native backend and ability to run algorithms in hybrid distributed - CPU/GPU environments

Competitive Positioning

- SparkML / MLLib Bag of Algorithms- Good for Demos, difficult to extend.
- Apache SystemML Incubating Requires its own scripting language, Spark only execution
- Tensor Flow Requires own cluster (at best can piggy-back off of Spark) - Python Based
- Sklearn / R Single Node Bound
 - SparkR PySpark: Not actually full sklearn / R- only API for using standard SparkML functions (common misconception)

An 'Ideal' Language for Distributed Math/DS

- Mathematically Expressive
- Based in another language
- Backend independent
- Algebraic Optimizer

Mahout-Samsara

Mahout-Samsara is an easy-to-use domain-specific language (DSL) for large-scale machine learning on distributed systems like Apache Spark/Flink

- •Uses **Scala** as programming/scripting environment
- algebraic expression optimizer for distributed linear algebra
 - -provides a translation layer to distributed engines
 - -Support for Spark, Flink DataSets and H2O
- System-agnostic, R-like DSL; actual formula from (d)spca:

$$G = BB^{T} - C - C^{T} + \xi^{T} \xi s_{q}^{T} s_{q}$$

val
$$G = B %*% B.t - C - C.t + (ksi dot ksi) * (s_q cross s_q)$$

System Agnostic R-Like DSL

```

```

Samsara: Data Types

```
Scalar real values
In-memory vectors

-dense

-2 types of sparse
val v = dvec(1, 0, 5)

val w = svec((0 -> 1)::(2 -> 5)::Nil)
In-memory matrices

-sparse and dense

-a number of specialized matrices
val A = dense((1, 0, 5),

(2, 1, 4),

(4, 3, 1))
```

Samsara: Data Types- DRMs

Distributed Row Matrices (DRM)

- -huge matrix, partitioned by rows
- -lives in the main memory of the cluster
- –provides small set of parallelized operations
- -lazily evaluated operation execution

```
val drmA = drmDfsRead(...)
```

Features (1)

Matrix, vector, scalar operators:

in-memory, distributed

Slicing operators

Assignments (in-memory only)

Vector-specific

drmA %*% drmB

A %*% x

A.t %*% drmB

A * B

A(5 until 20, 3 until 40)

A(5, ::); A(5, 5)

x(a to b)

A(5, ::) := x

A *= B

A =: B; 1 /:= x

x dot y; x cross y

Features (2)

Summaries

A.nrow; x.length; A.colSums;

B.rowMeans;

A.norm

val x = solve(A, b)

Solving linear systems

In-memory decompositions

```
val (inMemQ, inMemR) = qr(inMemM)
val ch = chol(inMemM)
val (inMemV, d) = eigen(inMemM)
val (inMemU, inMemV, s) =
svd(inMemM)
```

Features (3)

```
Distributed decompositions
```

```
val (drmQ, inMemR) = thinQR(drmA)
val (drmU, drmV, s) =
  dssvd(drmA, k = 50, q = 1)
```

Caching of DRMs

```
val drmA_cached = drmA.checkpoint()
drmA_cached.uncache()
```

Unary Operators

In-Core

```
mahout> val mxA = dense((1,2,3),(3,4,5))
mxA: org.apache.mahout.math.DenseMatrix =
 0 \Rightarrow \{0:1.0,1:2.0,2:3.0\}
 1 \Rightarrow \{0:3.0,1:4.0,2:5.0\}
mahout> mlog(mxA)
res2: org.apache.mahout.math.Matrix =
 0 => {1:0.6931471805599453,2:1.0986122886681098}
 1 \Rightarrow \{0:1.0986122886681098, 1:1.3862943611198906, 2:1.6094379124341003\}
mahout> msignum(mxA)
res3: org.apache.mahout.math.Matrix =
 0 \Rightarrow \{0:1.0,1:1.0,2:1.0\}
 1 \Rightarrow \{0:1.0,1:1.0,2:1.0\}
```

In-Core (Contd)

Distributed Row Matrix (DRM)

```
mahout> val drmA = drmParallelize(mxA)

mahout> dlog(drmA).collect

res10: org.apache.mahout.math.Matrix =

Mahout Decomposition Algorithms

The goal of the Mahout project is to enable users to 'roll their own' algorithms. That said, there are a few decomposition algorithms we provide to make that experience much smoother. Namely,

- Distributed Stochastic Singular Value Decomposition
- Distributed Stochastic Principal Component Analysis
- Distributed thinQR

Linear Regression

•Let's predict customer rating of a cereal brand based on its ingredients

X = weights of **ingredients**

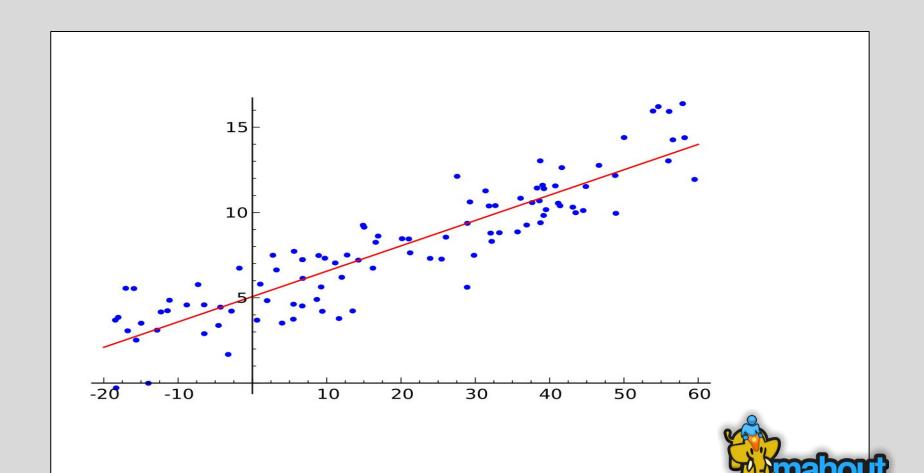

y = customer rating

•Assumption: target variable y generated by linear combination of feature matrix X with parameter vector $\boldsymbol{\beta}$, plus noise $\boldsymbol{\epsilon}$

$$y = X\beta + \varepsilon$$

•Goal: find estimate of the parameter vector $\boldsymbol{\beta}$ that explains the data well

Data Ingestion

•Usually: load dataset as DRM from a distributed filesystem:

```
val drmData = drmDfsRead(...)
```

•Simple dataset for our example:

Data Preparation

•Cereals example: target variable y is customer rating, weights of ingredients are features X

•extract X as DRM by slicing, fetch y as in-core vector

```
val drmX = drmData(::, 0 until 4)
val y = drmData.collect(::, 4)
```

armx				У
2	2	10.5	10	29.509541
1	2	12	12	18.042851
1	1	12	13	22.736446
2	1	11	13	32.207582
1	2	12	11	21.871292
2	1	16	8	36.187559
6	2	17	1	50.764999
3	2	13	7	40.400208
3	3	13	4	45.811716

Estimating β

- •Ordinary Least Squares: minimizes the sum of residual squares between true target variable and prediction of target variable
- •Closed-form expression for estimation of β as

$$\hat{\boldsymbol{\beta}} = (\boldsymbol{X}^T \boldsymbol{X})^{-1} \boldsymbol{X}^T \boldsymbol{y}$$

•Computing **X**^T**X** and **X**^T**y** is as simple as:

```
val drmXtX = drmX.t %*% drmX
val drmXty = drmX.t %*% y
```

Estimating β

•Solve the following linear system to get least-squares estimate of ß

$$X^T X \hat{\beta} = X^T y$$

- •Fetch X^TX and X^Ty onto the driver and use an in-core solver
 - -assumes X^TX fits into memory
 - -use analogous to R's solve() function

```
val XtX = drmXtX.collect
val Xty = drmXty.collect(::, 0)
val betaHat = solve(XtX, Xty)
```

Estimating β

•Solve the following linear system to get least-squares estimate of ß

$$X^T X \hat{\beta} = X^T y$$

- •Fetch X^TX and X^Ty onto the driver and use an in-core solver
 - -assumes X^TX fits into memory
 - –use analogous to R's solve() function

```
val XtX = drmXtX.collect
val Xty = drmXty.collect(::, 0)
val betaHat = solve(XtX, Xty)
```

→ We have implemented distributed linear regression!

Goodness of fit

•Prediction of the target variable is simple matrix-vector multiplication

$$\hat{y} = X \hat{\beta}$$

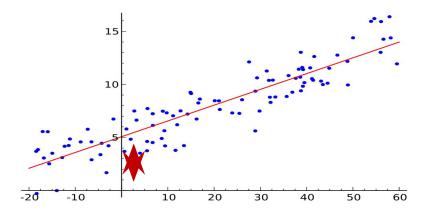

•Check L2 norm of the difference between true target variable and our prediction

```
val yHat = (drmX %*% betaHat).collect(::, 0)
(y - yHat).norm(2)
```

Adding a bias term

- •Bias term left out so far
 - constant factor added to the model, "shifts the line vertically"
- •Common trick is to add a column of ones to the feature matrix
 - -bias term will be learned automatically

Adding a bias term

```
•How do we add a new column to a DRM?
  → mapBlock() allows for custom modifications of the matrix
val drmXwithBiasColumn = drmX.mapBlock(ncol = drmX.ncol + 1) {
  case(keys, block) =>
    // create a new block with an additional column
    val blockWithBiasCol = block.like(block.nrow, block.ncol+1)
    // copy data from current block into the new block
    blockWithBiasCol(::, 0 until block.ncol) := block
    // last column consists of ones
    blockWithBiasColumn(::, block.ncol) := 1
    keys -> blockWithBiasColumn
```

Adding a bias term (easy way)

```
val drmXwithBiasColumn = drmX cbind 1
```

Durbin Watson Test Statistic

The <u>Durbin Watson Test Statistic</u> is used to test for <u>autocorrelation</u> among the error terms of a linear regression, a situation commonly faced in time series analysis.

$$d = rac{\sum_{t=2}^T (e_t - e_{t-1})^2}{\sum_{t=1}^T e_t^2}.$$

Durbin Watson Test Statistic

We can create our own Durbin Watson function

```
d = rac{\sum_{t=2}^{T}(e_t - e_{t-1})^2}{\sum_{t=2}^{T}e_t^2}
def durbinWatson(error: DrmLike[Int]) = {
    //https://en.wikipedia.org/wiki/Durbin%E2%80%93Watson_statistic
    To test for positive autocorrelation at significance \alpha, the test statistic d
    is compared to lower and upper critical values (dL,\alpha and dU,\alpha):
        If d < dL, \alpha, there is statistical evidence that the error terms are positively autocorrelated.
        If d > dU, \alpha, there is no statistical evidence that the error terms are positively autocorrelated.
        If dL, \alpha < d < dU, \alpha, the test is inconclusive.
    val e = error(1 until error.nrow.toInt, 0 until 1)
    val e_t_1 = error(0 until error.nrow.toInt - 1, 0 until 1)
    val numerator = (e - e_t_1).assign(Functions.SQUARE).colSums
    val denominator = error.assign(Functions.SQUARE).colSums
    numerator / denominator
```

Cochrane-Orcutt Procedure

The <u>Cochrane-Orcutt estimation</u> adjusts for autocorrelation in the error term, e.g. "tries to correct the betas" for autocorrelation.

If the Durbin Watson Test Statistic indicates there is autocorrelation then the parameter estimates (betas) are biased and must be corrected.

We seek new betas that produce a model which does not suffer from autocorrelation

In short this is achieved by:

$$egin{aligned} arepsilon_t &=
ho arepsilon_{t-1} + e_t \ y_t -
ho y_{t-1} &= lpha (1-
ho) + eta (X_t -
ho X_{t-1}) + e_t \end{aligned}$$

Cochrane-Orcutt Procedure

```
def cochraneOrcutt( drmX: DrmLike[Int],
                    drmY: DrmLike[Int]) = {
   // https://en.wikipedia.org/wiki/Cochrane%E2%80%930rcutt_estimation
    val drmX_lag1 = drmX(0 until error.nrow.toInt - 1, 0 until 1)
    val drmY_lag1 = drmY((0 until error.nrow.toInt - 1, 0 until 1))
    var beta = ols(drmX, drmY).checkpoint()
    val yFitted = (drmX %*% beta).checkpoint()
    val error = yFitted - drmY
                                                                                    \varepsilon_t = \rho \varepsilon_{t-1} + e_t
    val rho = ols(error(1 until error.nrow.toInt, 0 until 1),
                    error(0 until error.nrow.toInt - 1, 0 until 1)).get(0,0)
    // e = rho*e t-1
    val drmYprime = drmY(1 until error.nrow.toInt, 0 until 1) - drmY_lag1 * rho
    val drmXprime = drmX(1 until error.nrow.toInt, 0 until 1) - drmX_lag1 * rho →
                                                                y_t-
ho y_{t-1}=lpha(1-
ho)+eta(X_t-
ho X_{t-1})+e_t
    var betaPrime = ols(drmXprime, drmYprime)
    val b0 = betaPrime(0,0) / (1 - rho)
    betaPrime(0.0) = b0
    betaPrime
```

Mahout+Zeppelin integration relies on Zeppelin feature known as **ResourcePools**In short this method consists of:

- 1. Do analysis in Apache Mahout
- 2. Write results to tab-separated string (e.g. a string that looks like a tsv file)
- 3. Put string in ResourcePool
- 4. Fetch string from ResourcePool in R/Python
- 5. Read into DataFrame as you would a tsv file
- 6. Leverage R/Python plotting libraries

```
%flinkMahout
                                                                                                      FINISHED D ※ 間 @
                                                                                                                                %sparkMahout
                                                                                                                                                                                                                                     FINISHED ▷ XX III @

About Andrew

Andrew Musselman

Committer and PMC - Apache Mahout

Chief Data Scientist, Accenture

@akm

akm@apache.org

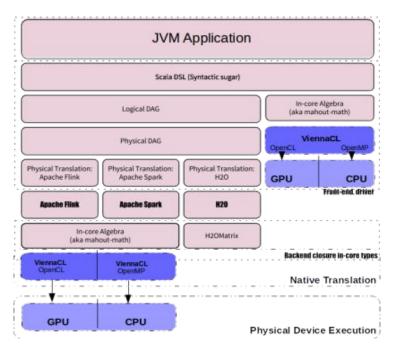

The Mahout Stack (Current)

Scala DSL (Syntactic sugar) Logical DAG In-core Algebra (aka mahout-math) Physical DAG Physical Translation: Apache Flink Physical Translation: Apache Spark Physical Translation: H2O Front-en	Application code (Scala or shell script)			
Physical DAG Physical Translation: Apache Flink Physical Translation: Apache Spark Physical Translation: Physical Translation: H2O Froat-eil				
Physical Translation: Apache Flink Physical Translation: Physical Translation: H2O Front-en		Logical DAG		In-core Algebra (aka mahout-math)
Apache Flink Apache Spark H2O Front-en		Physical DAG		
	Apache Flink	Apache Spark	H2O	Front-end, driv
In-core Algebra (aka mahout-math) H2OMatrix			H2OMatrix	

Reproduced with permission from 'Apache Mahout: Beyond MapReduce'

The Mahout Stack (Future)

Reproduced with permission from 'Apache Mahout: Beyond MapReduce'

Runtime and Optimizations

- Execution is deferred, user composes logical operators
- Computation triggers
 optimization and execution
- Optimization factors
 - –Size of operands
 - –Orientation of operands
 - -Partitioning
 - –Shared computational paths

```
val drmC = drmA.t %*% drmA
```

```
drmI.dfsWrite(path)
val inMemV = (drmU %*% drmM).collect
```

Example with matrix multiplication:

- •5 physical operators for drmA %*% drmB
- •2 operators for drmA %*% inMemA
- •1 operator for drm A %*% x
- •1 operator for x %*% drmA

Runtime and Optimizations

```
    Common computational paths

                                     ((A + B)' \%*\% (A + B) -> self-square(A + B)
```

- Tracking identically partitioned sets
- ("zip" vs. "join" judgements)
- Tracking data deficiencies
 - -automatic fixes
- Algebraic cost reducing rewrites
- •Unary operator fusion $dlog(X * X) \rightarrow elementwise-apply [x => log(x * x)]$
- Elements of cost based optimizations
- Product parallelism decisions
- Explicit and implicit optimization barriers
 - -control the scope of optimization

(missing or duplicate rows)

(Expr t) t -> Expr

("slim" vs. "wide")

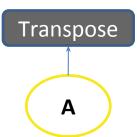

•Computation of A^TA in example

•Computation of A^TA in example

Naïve execution

1st pass: transpose A (requires repartitioning of A)

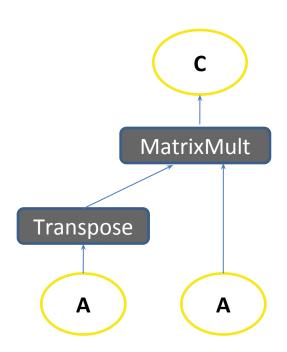

•Computation of A^TA in example val C = A.t %*% A

Naïve execution

1st pass: transpose A(requires repartitioning of A)

2nd pass: multiply result with A (expensive, potentially requires repartitioning again)

Computation of A^TA in example

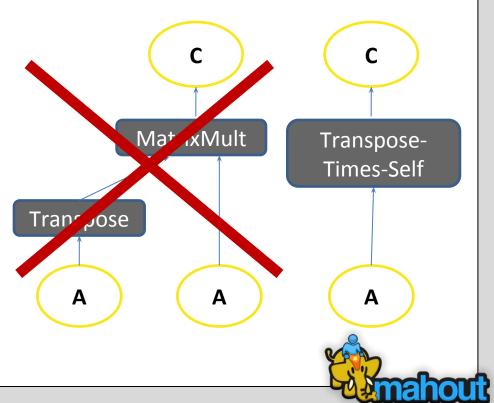

val C = A.t %*% A
Naïve execution

1st pass transpose A (requires in partitioning of A)

2nd pass: multiply a sult with A (expensive, potentially equires repart aoning again)

Logical optimization

Optimizer rewrites plan to use specialized logical operator for *Transpose-Times-Self* matrix multiplication

$$A^T A = \sum_{i=0}^m a_{i\bullet} a_{i\bullet}^T$$

•Mahout Samsara computes A^TA via **row-outer-product** formulation –executes in a single pass over row-partitioned A

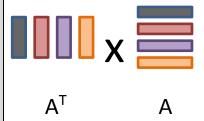

$$A^T A = \sum_{i=0}^m a_{i\bullet} a_{i\bullet}^T$$

Α

$$A^T A = \sum_{i=0}^m a_{i\bullet} a_{i\bullet}^T$$

$$A^T A = \sum_{i=0}^m a_{i\bullet} a_{i\bullet}^T$$

$$A^{\mathsf{T}} \qquad A \qquad \mathbf{a}_{1 \cdot \mathsf{T}}$$

$$A^T A = \sum_{i=0}^m a_{i\bullet} a_{i\bullet}^T$$

$$A^{\mathsf{T}} \qquad A \qquad \mathbf{a}_{1 \cdot \mathsf{T}} \qquad \mathbf{a}_{2 \cdot \mathsf{T}} \qquad \mathbf{a}_{2 \cdot \mathsf{T}}$$

$$A^T A = \sum_{i=0}^m a_{i\bullet} a_{i\bullet}^T$$

$$\mathbf{A}^{\mathsf{T}} \qquad \mathbf{A} \qquad \mathbf{a}_{1 \cdot \mathsf{T}} \qquad \mathbf{a}_{2 \cdot \mathsf{T}} \qquad \mathbf{a}_{3 \cdot \mathsf{T}} \\ \mathbf{a}_{1 \cdot \mathsf{T}} \qquad \mathbf{a}_{2 \cdot \mathsf{T}} \qquad \mathbf{a}_{3 \cdot \mathsf{T}} \\ \mathbf{a}_{3 \cdot \mathsf{T}} \qquad \mathbf{a}_{3 \cdot \mathsf{T}}$$

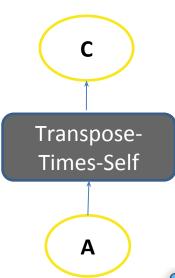

$$A^T A = \sum_{i=0}^m a_{i\bullet} a_{i\bullet}^T$$

Physical operators for the distributed computation of A^TA

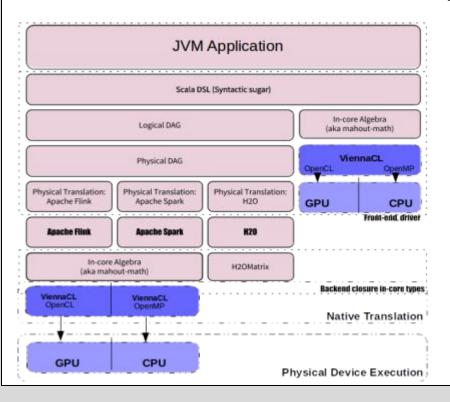

Physical Operators for Transpose-Times-Self

•Two physical operators (concrete implementations) available for *Transpose-Times-Self* operation

- -standard operator AtA
- –operator *AtA_slim*, specialized implementation for tall & skinny matrices
- Optimizer must choose
 - –currently: depends on user-defined
 threshold for number of columns
 –ideally: cost based decision, dependent on
 estimates of intermediate result sizes

The Mahout Stack + Native (Future)

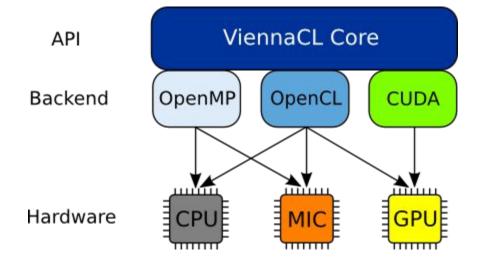

Current work: A plugin to break mahout out of the restrictions of the JVM by implementing native operations for in-core matrices using ViennaCL. This Provides GPU and multi-threaded native CPU Acceleration for DRM operations on the back end of a cluster.

Native OpenMP and GPU Acceleration will not require any change in syntax.

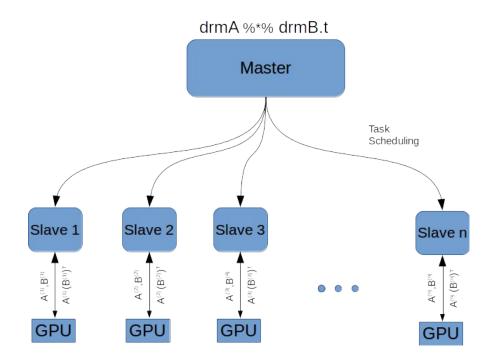

Why ViennaCL

GPU Compute

With GPU Integration, Mahout syntax will not change at all.

Creating a Framework for new Algorithms https://github.com/apache/mahout/pull/246

R and Mahout in days of old: "Loose bag of algorithms"

Consistent API

- Approach of sklearn, adopted by SparkML
- Makes 'Pipelines' easier.

Mahout approach somewhere in the middle

Several Types of Models

- Regressor: Many inputs -> one continuous output
 - OLS
 - GLM
- Transformer: Many inputs -> many outputs
 - Feature Normalizer
 - Neural Networks
- Classifier: Many inputs -> choose a classification
 - K-Means
- Pipelines: A series of models
- Ensembles: Output of several models combined into one

Goal: Consistent interface

Methods such as '.fit' '.predict' and '.transform' where possible

Similar to sklearn interface

Parameter space that can be searched similar to sklearn 'gridCVSearch'

Many 'prototype' models part of pull request

Transformers:

- Mean center (used in Eigenfaces Demo)
- Feature Normalizer

Regressors:

Ordinary Least Squares

We're still trying to figure out where fitness tests, ALS, and procedures like Cochrane-Orcutt belong, Our Algorithm API is still [WIP].

Hoping to integrate with Spark Pipelines

- Mahout algos as part of SparkML pipeline and vice versa

Overview

- Getting to Know Mahout
- Rolling our own algorithms
- Future: What's Coming ...
- Conclusion and Questions

What's Next for Apache Mahout and You?

- 1. Ask us some questions now.
- 2. Go home and start using Mahout:
 - a. Include in your compiled jars OR
 - b. Download Zeppelin and play in notebook
- 3. Join the mailing lists
- 4. Get the book
- 5. Contribute!

Apache Mahout: Beyond Map Reduce

Bonus Material

"But I don't have a 5-node YARN cluster to play with..."

Yes you do.
